

JAVA - URL PROCESSING

https://www.tutorialspoint.com/java/java_url_processing.htm

Copyright © tutorialspoint.com

URL stands for Uniform Resource Locator and represents a resource on the World Wide Web, such as a Web page or FTP directory.

This section shows you how to write Java programs that communicate with a URL. A URL can be broken down into parts, as follows –

```
protocol://host:port/path?query#ref
```

Examples of protocols include HTTP, HTTPS, FTP, and File. The path is also referred to as the filename, and the host is also called the authority.

The following is a URL to a web page whose protocol is HTTP –

```
https://www.amrood.com/index.htm?language=en#j2se
```

Notice that this URL does not specify a port, in which case the default port for the protocol is used. With HTTP, the default port is 80.

URL Class Methods

The **java.net.URL** class represents a URL and has a complete set of methods to manipulate URL in Java.

The URL class has several constructors for creating URLs, including the following –

Sr.No.	Method & Description
1	<p>public URL(<i>String</i> protocol, <i>String</i> host, <i>int</i> port, <i>String</i> file) throws MalformedURLException</p> <p>Creates a URL by putting together the given parts.</p>
2	<p>public URL(<i>String</i> protocol, <i>String</i> host, <i>String</i> file) throws MalformedURLException</p> <p>Identical to the previous constructor, except that the default port for the given protocol is used.</p>
3	<p>public URL(<i>String</i> url) throws MalformedURLException</p> <p>Creates a URL from the given String.</p>

4 **public URL *URLcontext, String url* throws MalformedURLException**

Creates a URL by parsing together the URL and String arguments.

The URL class contains many methods for accessing the various parts of the URL being represented. Some of the methods in the URL class include the following –

Sr.No.	Method & Description
1	public String getPath Returns the path of the URL.
2	public String getQuery Returns the query part of the URL.
3	public String getAuthority Returns the authority of the URL.
4	public int getPort Returns the port of the URL.
5	public int getDefaultPort Returns the default port for the protocol of the URL.
6	public String getProtocol Returns the protocol of the URL.
7	public String getHost Returns the host of the URL.

8	public String getHost Returns the host of the URL.
9	public String getFile Returns the filename of the URL.
10	public String getRef Returns the reference part of the URL.
11	public URLConnection.openConnection throws IOException Opens a connection to the URL, allowing a client to communicate with the resource.

Example

The following URLEDemo program demonstrates the various parts of a URL. A URL is entered on the command line, and the URLEDemo program outputs each part of the given URL.

```
// File Name : URLEDemo.java
import java.net.*;
import java.io.*;

public class URLEDemo {

    public static void main(String [] args) {
        try {
            URL url = new URL("https://www.amrood.com/index.htm?language=en#j2se");

            System.out.println("URL is " + url.toString());
            System.out.println("protocol is " + url.getProtocol());
            System.out.println("authority is " + url.getAuthority());
            System.out.println("file name is " + url.getFile());
            System.out.println("host is " + url.getHost());
            System.out.println("path is " + url.getPath());
            System.out.println("port is " + url.getPort());
            System.out.println("default port is " + url.getDefaultPort());
            System.out.println("query is " + url.getQuery());
            System.out.println("ref is " + url.getRef());
        } catch (IOException e) {
            e.printStackTrace();
        }
    }
}
```

```
}
}
```

A sample run of the this program will produce the following result –

Output

```
URL is https://www.amrood.com/index.htm?language=en#j2se
protocol is http
authority is www.amrood.com
file name is /index.htm?language=en
host is www.amrood.com
path is /index.htm
port is -1
default port is 80
query is language=en
ref is j2se
```

URLConnections Class Methods

The openConnection method returns a **java.net.URLConnection**, an abstract class whose subclasses represent the various types of URL connections.

For example –

- If you connect to a URL whose protocol is HTTP, the openConnection method returns an HttpURLConnection object.
- If you connect to a URL that represents a JAR file, the openConnection method returns a JarURLConnection object, etc.

The URLConnection class has many methods for setting or determining information about the connection, including the following –

Sr.No.	Method & Description
1	Object getContent Retrieves the contents of this URL connection.
2	Object getContentClass[] classes Retrieves the contents of this URL connection.
3	String getContentEncoding Returns the value of the content-encoding header field.

4	int getLength Returns the value of the content-length header field.
5	String getContentType Returns the value of the content-type header field.
6	int getLastModified Returns the value of the last-modified header field.
7	long getExpiration Returns the value of the expired header field.
8	long getIfModifiedSince Returns the value of this object's ifModifiedSince field.
9	public void setDoInput <i>booleaninput</i> Passes in true to denote that the connection will be used for input. The default value is true because clients typically read from a URLConnection.
10	public void setDoOutput <i>booleanoutput</i> Passes in true to denote that the connection will be used for output. The default value is false because many types of URLs do not support being written to.
11	public InputStream getInputStream throws IOException Returns the input stream of the URL connection for reading from the resource.
12	

public OutputStream getOutputStream throws IOException

Returns the output stream of the URL connection for writing to the resource.

13

public URL getURL

Returns the URL that this URLConnection object is connected to.

Example

The following URLConnectionDemo program connects to a URL entered from the command line.

If the URL represents an HTTP resource, the connection is cast to HttpURLConnection, and the data in the resource is read one line at a time.

```
// File Name : URLConnDemo.java
import java.net.*;
import java.io.*;

public class URLConnDemo {

    public static void main(String [] args) {
        try {
            URL url = new URL("https://www.amrood.com");
            URLConnection urlConnection = url.openConnection();
            HttpURLConnection connection = null;
            if(urlConnection instanceof HttpURLConnection) {
                connection = (HttpURLConnection) urlConnection;
            } else {
                System.out.println("Please enter an HTTP URL.");
                return;
            }

            BufferedReader in = new BufferedReader(
                new InputStreamReader(connection.getInputStream()));
            String urlString = "";
            String current;

            while((current = in.readLine()) != null) {
                urlString += current;
            }
            System.out.println(urlString);
        } catch(IOException e) {
            e.printStackTrace();
        }
    }
}
```

A sample run of this program will produce the following result –

Output

```
$ java URLConnDemo
```

```
.....a complete HTML content of home page of amrood.com.....
```
